pgfopts — LaTeX package options with pgfkeys*

Joseph Wright[†]

Released 2010/05/01

Abstract

Using key-value options for packages and macros is a good way of handling large numbers of options with a clean interface. The pgfkeys package provides a very well designed system for defining and using keys, but does not make this available for handling LaTeX class and package options. The pgfopts package adds this ability to pgfkeys, in the same way that kvoptions extends the keyval package.

1 Introduction

The key-value method for optional arguments is very popular, as it allows the class or package author to define a large number of options with a simple interface. A number of packages can be used to provide the key management system, most of which load or extent the parent keyval package. On its own, keyval can only be used for parsing the arguments of macros. However, a number of packages have extended the method to processing LaTeX class and package options. This processing is made available as part of two general-purpose packages xkeyval

^{*}This file describes version v2.0, last revised 2010/05/01.

and kvoptions; both allow the author of a class or package to process key-value options given at load-time.

The pgfkeys package provides a somewhat different key-value system to keyval and derivatives. This uses a completely different model for defining and using keys, although for the end-user the result appears very similar. The pgfopts package allows keys defined with pgfkeys to be used as class or package options, in the same way that kvoptions extends keyval.

Users of pgfopts should be familiar with the general methods used by pgfkeys. These are outlined in the manual for the Tikz and pgf bundle.

2 Installation

The package is supplied in dtx format and as a pre-extracted zip file, pgfopts.tds.zip. The later is most convenient for most users: simply unzip this in your local texmf directory and run texhash to update the database of file locations. If you want to unpack the dtx yourself, running tex pgfopts.dtx will extract the package whereas latex pgfopts.dtx will extract it and also typeset the documentation.

Typesetting the documentation requires a number of packages in addition to those needed to use the package. This is mainly because of the number of demonstration items included in the text. To compile the documentation without error, you will need the packages:

- csquotes
- helvet
- hypdoc
- listings
- Imodern
- mathpazo
- microtype

3 Using the package

3.1 Creating options

To create package or class options for use with pgfopts, it is only necessary to define the appropriate keys. Taking as an example a package "MyOwnPackage", which uses the prefix MOP on internal macros, creating keys would take the form:

```
\pgfkeys{
/MOP/.cd,
keyone/.code=\wlog{Value '#1' given},
keytwo/.store in=\MOP@store
```

Here, keyone simply writes its argument to the log, while keytwo stores the value given in the \MOP@store macro.

An important point to notice is that the key names *do not* contain a space. This is because the LaTeX kernel removes spaces from options before they are passed to the class or package. Spaces can occur in the path to the key, but not in the key name itself. This restriction only applies to keys used as options.

3.2 Processing options

\ProcessPgfOptions

The \ProcessPgfOptions macro is used to process package or class options using pgfkeys. When used in a package, it will also examine the available class options, and use any which match declared package options. \ProcessPgfOptions requires the pgfkeys key $\langle path \rangle$ to search for options. Thus for the example of MyOwnPackage given in the previous section, the appropriate call would be

\ProcessPgfOptions{/MOP}

Alternatively, \ProcessPgfOptions can be given with a star:

\ProcessPgfOptions*

The macro will then use the current file name as the path. This will be the name of the current class or package, as appropriate.

\ProcessPgfPackageOptions

As a complement to \ProcessPgfOptions, the macro \ProcessPgfPackageOptions is also provided. As the name indicates, this is intended for use in packages. It does *not* examine the list of global class options, processing only the list of options given for the class itself. If used in a class, the behaviour will be identical to \ProcessPgfOptions.
